Purpose: The aim of this study was to conduct a meta-synthesis to analyze qualitative research findings and thereby understand patients' experiences of whiplash-associated disorders (WAD) and the injury-recovery process.

Materials and methods: A qualitative meta-synthesis, which is an interpretive integration of existing qualitative findings, was performed. The databases PubMed, PsychINFO, Scopus, and Web of Science were searched. The Critical Assessment Skills Programme was used to assess the quality of the included studies.

Results: Four studies were included. The synthesis resulted in several codes, 6 categories, and 3 themes (distancing from normalcy, self-efficacy in controlling the life situation after the injury, and readjustment and acceptance) that described the participants' pain beliefs, their WAD-related life situation and their future expectations and acceptance. Changes in self-image were difficult to cope with and likely led to perceived stigmatization. Struggling with feelings of loss of control appeared to lead to low confidence and insecurity. Focusing on increasing knowledge and understanding the pain and its consequences were believed to lead to better strategies for handling the situation. Furthermore, recapturing life roles, including returning to work, was challenging, but an optimistic outlook reinforced symptom improvements and contributed to feelings of happiness.

Conclusion: The results of the present study provide a comprehensive understanding of patients' complex, multifaceted experiences of WAD, and the injury-recovery process. The findings can guide us in the development of new ways to evaluate and manage WAD. The results also indicate that a more patient-centered approach is needed to determine the depth and breadth of each patient's problems.

Keywords: whiplash-associated disorders, control, self-efficacy, happiness, life situation

Introduction

The process of designing next-generation outcomes and management methods to better meet the needs of patients with whiplash-associated disorders (WAD) must involve a broader approach than is currently used. Because the outcome measures and management methods used for WAD are mostly based on studies at group level using standard measures but not based on an individual's specific needs, it is important to explore the experiences of patients with WAD during the process from injury to recovery.

In the context of WAD, there is no accepted standardized definition for recovery. Sterling et al¹ defined the prognosis for clinical recovery by identifying 3 pathways through a trajectory-modeling analysis in which the prognostic factor was the severity of

the initial pain-related disability (mild, moderate, or severe) measured at the group level and using standard measures. However, at the individual level, patients themselves most likely define recovery differently depending on their life situation. Thus, patients' thoughts regarding the injury-recovery process could be significant for their symptom management.

Efforts to manage WAD in current practice still struggle to find the most effective ways to solve pain- and disability-related problems during the recovery process. Exercise as a management method has been studied and is recommended extensively to facilitate recovery, as described in a recent systematic review.² However, the conclusion of that review was that there was no evidence that general exercise interventions led to long-term improvements.² Patient education³ and advice⁴ are often used, either alone or in combination with other methods, to stimulate recovery from WAD. However, the evidence for education is equivocal, and related trials have shown small effects.³ The difficulties of finding effective treatment and management strategies for WAD might be due to the complexity of the disorder and a great variation of pain-related problems between individuals, which clinicians and researchers have not fully comprehended. To complement current practice, we must understand patients' experiences of WAD and determine what patients believe would support their recovery process.

The situation is similar for the outcomes used in the WAD context. Quantifying patients' perceptions of their WAD-related life situation is not easy. As a basis for determining what to measure and where to direct the management and treatment,^{5,6} the biopsychosocial model plays an important role in the WAD context. However, when only the biopsychosocial model is used, there is no guarantee that patients' perceptions of their WAD-related life situation will be addressed and targeted during evaluation and management. A description of patients' perceptions of their neck pain and how they experience the process from injury to recovery^{7,8} is important for modernizing the management of WAD. Thus, the aim of this study was to conduct a meta-synthesis to analyze qualitative research findings and thereby understand patients' experiences of WAD and the injury-recovery process.

Materials and methods

Design

A qualitative meta-synthesis was applied. Meta-synthesis is defined being as an interpretive integration of existing published qualitative findings.⁹

Data sources

The PubMed, PsychINFO, Scopus, and Web of Science databases were independently searched. Additionally, the reference lists of the included studies were manually screened to complement the database search. The following keywords were used in the indicated combinations: whiplash, whiplash associated disorders, WAD, expectations or beliefs, recovery, qualitative or phenomenography, and focus group or interview. The search was performed in June 2017, and the range of publication dates was not limited.

The inclusion criteria were as follows: qualitative original studies, reported in the English language, the sample comprised participants with WAD, data collected via individual interviews or via a combination of individual interviews and focus groups, and the results relevant to the aim of this meta-synthesis. The titles and abstracts were screened, and the full text of studies that fulfilled the inclusion criteria was evaluated.

Data extraction and quality assessment

Data were extracted by the first author and cross-checked by the other authors independently. The Critical Assessment Skills Programme (CASP) was used to assess the quality of the included studies.¹⁰ The CASP has been used extensively in previous qualitative reviews.¹¹⁻¹³ The CASP includes 10 statements (see Table 1) with the response alternatives yes/no/can't tell. All authors independently assessed the quality of the included studies to increase trustworthiness. Disagreements were resolved by consensus discussions among the authors.

Data synthesis and analysis

We applied the principles for analysis as recommended by Sandelowski and Barroso⁹ and Walsh and Downe.¹⁴ First, we tabulated the key findings from each study. Second, the quality of the studies was assessed using the CASP statements.¹⁰ Third, by reading and re-reading the results of the included studies, we attempted to capture all the relevant descriptors from the original text before synthesizing these finding into the results. Fourth, we used reciprocal translation, which aims to translate the included studies' findings one at a time into categories that the next study's findings can confirm or extend while allowing space for divergent and deviant data to refute the identified categories and add new categories. Finally, we synthesized the categories into themes, thus elucidating more refined meanings than each study alone could identify.

Table 1 The quality assessment by Critical Appraisal Skills Program (CASP) criteria; response options are Yes/No/Can't tell

CASP criteria	Bostick et al ¹⁷	Rydstad et al ¹⁸	Walton et al ¹⁶	Williamson et al ¹⁹
1. Was there a clear statement of the aims of the research?	Yes	Yes	Yes	Yes
2. Is a qualitative methodology appropriate?	Yes	Yes	Yes	Yes
3. Was the research design appropriate to address the aims of the research?	Yes	Yes	Yes	Yes
4. Was the recruitment strategy appropriate to aims of the research?	Yes	Yes	Yes	Yes
5. Were the data collected in a way that addressed the research issue?	Yes	Yes	Yes	Yes
6. Has the relationship between researcher and participants been adequately considered?	Yes	Yes	No	Yes
7. Have ethical issues been taken into consideration?	Yes	Yes	Yes	Yes
8. Was the data analysis sufficiently rigorous?	Yes	Yes	Yes	Yes
9. Is there a clear statement of findings?	Yes	Yes	Yes	Yes
10. How valuable was the research?	Very	Very	Very	Very

Trustworthiness of the meta-synthesis authors

The authors of this meta-synthesis are all senior researchers. All but one (LN) has extensive clinical and research experience in WAD-related health problems. All the authors have experience in qualitative research, but LN has a particularly extensive and varied experience with different qualitative designs and analysis methods. All the authors are well aware of the possible problems that reflexivity and preconceptions¹⁵ could cause in this type of study, and all authors reflected on these issues during the meta-analysis process.

Results

A total of 57 studies were identified in the first stage, and 4 studies were ultimately eligible for inclusion in this meta-synthesis. Figure 1 presents the study identification process. In total, 81 individuals with WAD were interviewed in the studies; see Table 2 for more details.

The results of the quality assessment of the included studies are presented in Table 1.

The synthesis resulted in 29 codes, 6 categories, and 3 themes. The themes were “distancing from normalcy, self-efficacy in controlling the life situation after the injury, and readjustment and acceptance”. The themes, categories, and codes are presented in Table 3.

Distancing from normalcy

Interference and loss

The participants talked about pain and other symptoms interfering with their lives and about the loss of hope, ability, social roles, autonomy, and spontaneity. The participants also noted that it was difficult to continue exercising even though they believed exercise was beneficial. The participants

Figure 1 PRISMA flow diagram

Abbreviations: PRISMA, Preferred Reporting Items for Systematic Reviews and Meta-Analyses; WAD, whiplash-associated disorders.

believed that they had lost the physical capacity they had before the injury,¹⁶ and they felt sad and helpless about all physical, psychological, and social losses that were consequences of WAD.^{16,17} The participants sought to resume the normalcy,¹⁷ autonomy, and spontaneity of life experienced before the accident.¹⁶

Existential uncertainty

WAD changed the participants' self-image,¹⁸ and the participants felt that their previous self-image was difficult to re-establish.¹⁶ The changes in self-image likely contributed to the participants' existential uncertainty and feelings of being

Table 2 Characteristics and key findings of the included studies

Reference	Country	Sample size	Mean age (years)	Aim	Setting	Key findings
Bostick et al ¹⁷	Canada	17 (2 males)	40.8	Explore experiences informing WAD-related pain beliefs	Physiotherapy and chiropractic clinics	<ul style="list-style-type: none"> • Medical cure (optimism, control over pain, generally an optimist) • Control (perceived severity of the injury/pain, understanding, control over daily demands, treatment success) • Emotions (ability to control one's pain, interference and loss, stigma) • Mystery (incongruence)
Rydstad et al ¹⁸	Sweden	9 (4 males)	40.6	Explore patients with long-term WAD experiences of participation, knowledge, and strategies gained for handling daily occupations 1 year after rehabilitation.	Hospital day-care rehabilitation clinic	<ul style="list-style-type: none"> • Chaos in life (loss of hope, loss of ability, loss of social roles, abandoned by those around) • A light in the tunnel (support, hope, new knowledge) • Managing long-term pain (strategies for managing, changed self-image, work resumption)
Walton et al ¹⁶	Canada	35 (11 males)	44.3	Describe the meaning of being recovered as perceived by persons with long-term neck pain of traumatic origin	Physiotherapy and chiropractic clinics	<ul style="list-style-type: none"> • Absent, or at least manageable symptoms • Participation in valued life roles • Having the physical capacity one ought to have • Feeling positive emotions • Autonomy and spontaneity • Re-establishing a satisfactory sense of self.
Williamson et al ¹⁹	UK	20 (8 males)	43	Identify beliefs about pain and recovery in individuals with WAD.	Physiotherapy clinics	<ul style="list-style-type: none"> • To move or not to move (movement is best, reasons not to move) • Believing you can do it (it's up to me, needing support, loss of confidence) • Fitting it all in • The way ahead (optimism, unsure about the future, need for realistic expectations)

Abbreviation: WAD, whiplash-associated disorders.

Table 3 The synthesized themes and categories from the initial findings in the included studies, shortened to codes

Codes	Categories	Themes
Loss of ability, confidence, slavery, loss of freedom, loss of hope, abandoned by those around, loss of social roles, interference	Interference and loss	Distancing from normalcy
Frustration, fear, distress, sadness, worry, negative moods, stigma, chaos, mystery, a riddle needing answers, incongruences, unsure about future, changed self-image	Existential uncertainty	
Controllable pain, to have control over daily demands, self-satisfaction, self-confidence, hope, beliefs influence self-confidence, pain controllability is influenced by pain severity	Perceived struggling with control	Self-efficacy in controlling the life situation after the injury
Learning to develop strategies for managing and control, understanding a need for support, understanding a need for realistic expectations	Knowledge and understanding	
Work resumption, independency, autonomy, participation in valued life roles, absent or manageable symptoms, a desire to get and stay well, restore preinjury daily function, have the physical capacity one ought to have, commitments make it difficult to concentrate on recovery, challenges in retaining a positive outlook about recovery	Recapture life roles	Readjustment and acceptance
Happiness, optimism, spontaneity, to re-establish a satisfactory sense of self, positive emotions, improvement in mood	Happiness	

Note: Categories describe meaning and content of the codes, and themes synthesize the meaning and content of categories.

stigmatized.^{17,18} The participants felt that other individuals without WAD and pain labeled them negatively because there was no visible evidence of their pain.¹⁷ The invisibility of pain also contributed to the participants' belief that others thought they were malingering.¹⁷

Self-efficacy in controlling the life situation after the injury

Perceived struggling with control

The participants struggled with their confidence in their ability to control their pain and daily life. Low perceived control

Journal of Pain Research downloaded from https://www.dovepress.com/ by 130.238.60.24 on 01-Nov-2018 For personal use only.

appeared to lead to low confidence and insecurity regarding the ability to manage injury-related problems and the future.¹⁹ In contrast, perceived positive outcomes of treatment contributed to increased perceived control.¹⁷ Additionally, support from health care staff and significant others was an important part of being able to control the situation.^{18,19} At the same time, some participants believed that they needed to take responsibility for the situation themselves to increase their ability to control it.¹⁹

The perceived severity,¹⁷ manageability,¹⁶ and realistic expectations¹⁹ of symptom development also influenced the participants' feelings of control. Severe symptoms were difficult to tolerate and manage and decreased the participants' beliefs and confidence regarding their ability to control the situation. The participants did not always know what worsened pain and other WAD-related symptoms. The participants tried to determine how to control their situation but did not often succeed. Consequently, their confidence in their ability to manage pain and participate in daily activities decreased.

Knowledge and understanding

Knowledge of how medication, pain, and other symptoms were associated was believed to make the situation more understandable and could lead to the development of better strategies for coping with the situation.^{17,18} Additionally, an understanding of the pain was believed to contribute to its elimination. However, when the expectations of recovery were not fulfilled quickly enough, confusion and conflicting thoughts about outcomes arose.¹⁷ The participants needed to prioritize different commitments according to how they believed their pain and other symptoms would be aggravated.¹⁹ Knowledge about and experiences of participation in physical activity were perceived to be beneficial,¹⁸ although physical activity was not always easy to prioritize.¹⁹

Readjustment and acceptance

Recapture life roles

Returning to work was perceived as a challenging outcome.¹⁸ The combination of expectations regarding recovery and daily experiences of fluctuating symptoms decreased the participants' confidence concerning the future¹⁹ and their return to work.¹⁸ Supportive health care staff, colleagues, and employers were of great importance in increasing the participants' confidence in their ability to return to work. Perceived work-related stress and aggravated symptoms decreased their confidence in their ability to return to work, while different adaptations of working conditions and acceptance of their

own physical and psychological limitations increased the participants' confidence regarding return to work.¹⁸

Happiness

The participants talked about the importance of being optimistic despite the pain and other symptoms,¹⁷ and their optimism was reinforced by perceived symptom improvements.¹⁹ They believed that an optimistic outlook on life would help improve their situation.¹⁷ Striving for normalcy aroused positive emotions such as hope¹⁸ and happiness.¹⁷ Additionally, emotional improvement was interpreted as getting better even when the pain and other symptoms did not necessarily decrease.¹⁶

Discussion

This meta-synthesis of patients' experiences of WAD and the injury-recovery process resulted in 3 themes – 1) distancing from normalcy, 2) self-efficacy in controlling the life situation after the injury, and 3) readjustment and acceptance – describing the participants' beliefs regarding pain, their WAD-related life situation and their future expectations and acceptance related to the recovery process. The content of the 3 themes, which improves our understanding of the complexity of WAD, can be summarized as follows (the numbers refer to the respective themes indicated above): (1) Patients' perceived feelings of not being their "usual self" when pain and other symptoms interfered with activities and social contacts were strong. (1) The changed self-image was difficult to cope with and likely led to perceptions of stigmatization. (2) Struggling with feelings of a loss of control appeared to lead to low confidence and insecurity. (2) Thus, reinforcing participants' self-efficacy in taking control over pain and daily activities emerged as important. (2) A focus on increasing knowledge and understanding the pain and its consequences was believed to lead to better strategies for handling the situation during the recovery process. Furthermore, (3) resuming life roles, including returning to work, was challenging, but being (3) optimistic reinforced symptom improvements and contributed to feelings of happiness.

Existential uncertainty and recovery expectations in recovery process

Holm et al²⁰ and Söderlund et al²¹ concluded that recovery expectations are important in the prognosis of WAD. Furthermore, these studies showed an association between disability²⁰ or engagement in activities²¹ and recovery expectations. Those with low expectations were more likely to report high disability²⁰ and low engagement in activities.²¹

In the current synthesis, one of the emerging categories was existential uncertainty, which consisted of codes such as distress, worry, stigma, chaos, unsure about the future, and changed self-image. These cognitions and emotions are likely to contribute to recovery expectations during the recovery process. Holm et al²⁰ stated that interventions should be targeted to recovery expectations to be beneficial. However, we might need to identify not only recovery expectations but also the components of the recovery expectations concept and then design intervention around the components that are problematic to the patient.^{21–23}

Chronic WAD has been shown to be predicted by initial high pain intensity, coping styles, depression, fear of movement,^{24–29} and catastrophizing.^{17,27,28,30,31} Several categories indicated by our results mirrored the predictors, which could be important to the recovery process, found in previous quantitative studies.

The existential uncertainty category consisted of codes such as feelings of fear, sadness, worry, and negative moods, among others. However, the category also contained codes such as stigma, chaos and mystery, which could contribute to catastrophizing; moreover, all of these codes could contribute negatively to the recovery process. Bring et al³² studied coping patterns in patients with acute WAD. The authors concluded that on days with high physical and psychological distress, the patients reported a high degree of catastrophizing.³²

Beliefs of being stigmatized, perceiving chaos in daily life, and believing that one's situation is a mystery or a riddle that requires answers demand different methodological actions from those currently being used in the evaluation and treatment of WAD. These beliefs may not have been addressed effectively in the current management of WAD and thus may not effectively support the recovery process.

Control and self-efficacy in recovery process

The perception of struggling with control was one of the categories in the theme “self-efficacy in controlling the life situation after the injury”. This category consisted of codes related to control, controllable pain, and having control over daily demands but also self-satisfaction, self-confidence, hope, and beliefs that influence self-confidence. These results could be interpreted as indication that we must identify various areas where perceived control is an issue when evaluating the life situation of patients with WAD. We must also identify the meanings and the levels of self-satisfaction, self-confidence, and perceived feelings of hope to offer better

tailored treatments for supporting the recovery process. The codes in the perceived struggling with control category also suggest that there is a strong need for coping strategies that affect perceived control over pain and activities, as demonstrated previously.³³

Furthermore, the knowledge and understanding category included codes related to learning to develop strategies for control and self-management and understanding the need for realistic expectations, indicating important factors to consider in the treatment of WAD. This finding is in line with recent guidelines in which educating through advice as part of treatment has been recommended.⁴ However, because evidence of education as an effective treatment strategy remains equivocal, and considering the present results regarding desired topics for gaining knowledge (e.g., strategies for control), there is a need to consider what content knowledge-enhancing education should involve for these patients from an individual's point of view.

Poor self-efficacy in activities is a strong predictor of long-term disability.^{26,29,34,35} Functional self-efficacy and catastrophizing had large direct effects on disability, and self-efficacy had the larger effect of these 2 variables.²⁹ In 1 study, patients who had high self-efficacy in activities at inclusion reported lower disability at a 3-month follow-up compared with those who reported low initial self-efficacy.³⁴ The theme “self-efficacy in controlling the life situation after the injury” supported the importance of self-efficacy and emotions and beliefs in relation to increasing or decreasing self-efficacy, as captured in previous studies. In contrast, the content of the theme “distancing from normalcy” and the related category interference and loss suggest that there are factors that can decrease one's self-efficacy in managing the WAD-related situation. To date, there has been little or no effort to systematically evaluate and manage the beliefs and emotions in the context of WAD. The closest attempts have involved measuring and increasing self-efficacy beliefs and perceived control over pain. Much remains to be accomplished to better support the recovery process.

Life roles and acceptance in recovery process

The recapture life roles category in the theme “Readjustment and acceptance” further described possible significant factors contributing to patients' beliefs in their capacity to handle the situation, i.e., a desire to get and stay well, resume preinjury daily functioning, have the expected physical capacity, handle commitments that make it difficult to concentrate on

recovery, and the challenges in retaining a positive outlook regarding recovery.

Approximately 50% of patients with WAD have long-term symptoms after their injury,^{1,24} and a large proportion are reported to have poor quality of life.³⁶ Additionally, 13–50% are unable to work or participate fully in their daily activities.³⁷ The category recapture life roles describes the importance of resuming work, gaining independence and autonomy, and participating in valued life roles. Patients with WAD are in the middle of their lives, a period when work and participation in life are highly valued. Additionally, these results indicate that better management strategies are needed to support return to work and daily life in general.

The category happiness described existing positive beliefs and emotions, such as optimism, spontaneity, re-establish a satisfactory sense of self, positive emotions, and improvement in mood, that are important to capture in evaluation and support during management. The happiness category is likely related to the concept of acceptance and thus possibly indicates the possible importance of acceptance and commitment therapy, where psychological inflexibility is targeted, as one of the treatment strategies in WAD supporting the recovery process.³⁸

We need new ideas for designing evaluation and management methods for the recovery process for patients with WAD.³⁹ Our results can be a starting point for the development of more individualized methods that support recovery better than the current methods do. For example, the 3 recovery pathways suggested by Sterling et al¹ could be complemented with the results of the present study and possibly applied in clinical practice at the individual level.

Strengths and limitations

The strengths of the study lie in its credibility, trustworthiness, and auditability. The credibility of data handling is important in meta-synthesis,¹⁴ meaning that the data remain true to their source. In our study, the codes are clearly recognizable in the included studies, thus implying high credibility. Trustworthiness is another important methodological issue. In our study, all the authors, who are senior researchers, independently checked each step of the analysis, implying high trustworthiness. Thus, we believe that our analysis and the results are both credible and trustworthy. Furthermore, to enhance auditability,^{9,14} we have transparently documented each phase of the meta-analysis, from search to synthesis. Another important methodological issue in qualitative research is transferability, i.e., whether the findings can be transferred to new settings.⁴⁰ The present

findings are in line with those of previous qualitative studies, e.g., those investigating the life situation of people living with another chronic condition.⁴¹

The number of included studies might be considered a limitation affecting the trustworthiness of the results. However, we conducted an intensive search of studies that was not limited in terms of publication year and found only 4 relevant papers. Several repeated searches of databases and reference lists yielded the same 4 studies, which we ultimately included. In qualitative studies, the sample size should not be so large that it aggravates the intensive analysis required. Ethically, it is also important to listen to patients' voices without delay to facilitate improved management of WAD in the future. The participants in the included studies also repeatedly talked about similar topics, thus providing confirmation that enhances the trustworthiness of our results. We believe that our results generally mirror the beliefs of patients with WAD.

It should be noted that in the study by Williamson et al,¹⁹ only the findings for their first aim were included as their second aim lay beyond the focus of this meta-synthesis.

The quality of the studies could be a limitation. Specifically, 1 study failed the quality evaluation. However, as Sandelowski et al⁴² wrote: "In general, studies should not be excluded for reasons of quality, because [...] there are wide variations in conceptions of the good, and in quality criteria". Thus, we decided to include the low-quality study.

Conclusion

The results of the present study with its 3 themes (distancing from normalcy, self-efficacy in controlling the life situation after the injury, and readjustment and acceptance) and the large variation in the contents (codes) of the themes provide a more comprehensive understanding of the complexity of WAD; patients' complex, multifaceted experiences of WAD; and the injury-recovery process. The results can guide the development of new ways to evaluate and manage WAD. These results also indicate that there is great demand for an approach based on individuals' specific needs to determine the depth of problems and how to support the recovery process.

Journal of Pain Research

Dovepress

Publish your work in this journal

The Journal of Pain Research is an international, peer reviewed, open access, online journal that welcomes laboratory and clinical findings in the fields of pain research and the prevention and management of pain. Original research, reviews, symposium reports, hypothesis formation and commentaries are all considered for publication.

The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/journal-of-pain-research-journal>
