I. INTRODUCTION

Hadronic decays of charmed mesons open a window to explore the interplay between weak and strong interactions. Based on flavor SU(3) symmetry, different topological amplitudes for two-body hadronic decays of D mesons can be extracted by diagrammatic approach [1–3] or factorization-assisted topological-amplitude approach [4]. Consequently, comprehensive measurements of their branching fractions (BFs) can not only test the theoretical calculations, but also shed light on the understanding of SU(3)-flavor symmetry-breaking effects in D decays [5].

Two-body D hadronic decays have been extensively investigated in previous experiments [6]. However, experimental knowledge of some singly Cabibbo-suppressed (SCS) decays involving four photons, e.g., \( D^0 \to \omega \pi^0, \eta \eta, \eta' \pi^0, \eta' \pi^0, \eta \eta \) and \( \eta' \eta \), is still poor due to low statistics and high backgrounds. The decay \( D^0 \to \omega \eta \) is particularly interesting, since it only occurs via \( W \)-internal emission and \( W \)-exchange, as shown in Fig. 1, and its decay BF is expected to be at the \( 10^{-3} \) level [2]. However, it has not yet been measured in any experiment.

Previously, the CLEO Collaboration reported the measurements of the BFs of \( D^0 \to \eta \pi^0, \eta \eta, \eta' \pi^0, \eta' \pi^0, \eta \eta \) [7,8]. During 2010 and 2011, a data sample with an integrated luminosity of 2.93 fb\(^{-1}\) [9] was collected with the BESIII detector at a center-of-mass energy \( \sqrt{s} = 3.773 \) GeV. In \( e^+e^- \) annihilations at this energy, \( D \) mesons are produced in pairs with no additional particles and can serve as an ideal test-bed to systematically study \( D \) decays. With this data sample, the BFs of the two-body hadronic decays \( D^0 \to \pi^\pm \pi^\mp \) [10] and \( D^0 \to \omega \eta, \eta \eta \) [11] have been previously measured using single-tagged and double-tagged events, respectively, in which one and two \( D \) mesons are reconstructed in each event. In this paper, we report the measurements of the BFs for \( D^0 \to \omega \eta, \eta \eta, \eta' \pi^0, \eta \eta \) and \( \eta' \eta \), by analyzing single-tag events using this data sample. Throughout this paper, the inclusion of charge-conjugate final states is implied.

II. BESIII DETECTOR AND MONTE CARLO SIMULATION

The BESIII detector in Beijing, China, is a cylindrical detector with a solid-angle coverage of 93% of 4\( \pi \) that operates at the BEPCII collider consisting of the following five main components. A 43-layer main drift chamber
(MDC) surrounding the beam pipe provides precise determinations of charged particle trajectories and ionization energy losses (dE/dx) for charged particle identification (PID). An array of time-of-flight counters (TOF) is located outside the MDC and provides additional information for PID. A CsI(Tl) electromagnetic calorimeter (EMC) surrounds the TOF and is used to measure energies of electromagnetic showers. A solenoidal superconducting magnet outside the EMC provides a 1 T magnetic field in the central tracking region of the detector. The iron flux return yoke of the magnet is instrumented with 9 layers in the barrel and 8 layers in the end-caps. More details of the BESIII detector are described in Ref. [12].

A GEANT4-based [13] Monte Carlo (MC) simulation software package, which includes the geometrical description of the detector and its response, is used to determine the detection efficiency and to estimate the potential backgrounds. An inclusive MC sample produced at the LUNDCHARM [19]. The inclusive MC sample corresponds to about 10 times the equivalent luminosity of data. To reject beam backgrounds are suppressed by requiring clusters to occur no later than 700 ns from the event start time. To reject photons from bremsstrahlung or from secondary interactions, the two-body D hadronic decays of interest are selected from combinations of π⁺, η, ω and η' mesons reconstructed using π⁺ → γγ, η → γγ, ω → π⁺π⁻π⁰ and η' → π⁺π⁻η decays, respectively. The D⁰ → ηη decay is also reconstructed using one η undergoing a γγ decay and the other decaying to the ηπ⁻π⁺ final state. In the following, we use ηγ and ηπ for the decay modes η → γγ and η → π⁺π⁻π⁰, respectively, but simply use η for the other D⁰ decays with a final-state η to represent the decay η → γγ.

The minimum distance of a charged track to the interaction point (IP) is required to be within 10 cm along the beam direction and within 1 cm in the perpendicular plane. The polar angle θ of a charged track with respect to the positron beam direction is required to satisfy |cos θ| < 0.93. PID is performed by using the dE/dx and TOF measurements to calculate confidence levels for pion and kaon hypotheses, CLx and CLK. Charged pions are required to satisfy CLx > CLK.

Photon candidates are chosen from isolated EMC clusters with energy larger than 25 (50) MeV if the crystal with the maximum deposited energy in that cluster is in the barrel (end-cap) region [12]. Clusters due to electronic noise or beam backgrounds are suppressed by requiring clusters to occur no later than 700 ns from the event start time. To reject photons from bremsstrahlung or from secondary interactions,

III. DATA ANALYSIS

The two-body D hadronic decays of interest are selected from combinations of π⁺, η, ω and η' mesons reconstructed using π⁺ → γγ, η → γγ, ω → π⁺π⁻π⁰ and η' → π⁺π⁻η decays, respectively. The D⁰ → ηη decay is also reconstructed using one η undergoing a γγ decay and the other decaying to the ηπ⁻π⁺ final state. In the following, we use ηγ and ηπ for the decay modes η → γγ and η → π⁺π⁻π⁰, respectively, but simply use η for the other D⁰ decays with a final-state η to represent the decay η → γγ.

The minimum distance of a charged track to the interaction point (IP) is required to be within 10 cm along the beam direction and within 1 cm in the perpendicular plane. The polar angle θ of a charged track with respect to the positron beam direction is required to satisfy |cos θ| < 0.93. PID is performed by using the dE/dx and TOF measurements to calculate confidence levels for pion and kaon hypotheses, CLx and CLK. Charged pions are required to satisfy CLx > CLK.

Photon candidates are chosen from isolated EMC clusters with energy larger than 25 (50) MeV if the crystal with the maximum deposited energy in that cluster is in the barrel (end-cap) region [12]. Clusters due to electronic noise or beam backgrounds are suppressed by requiring clusters to occur no later than 700 ns from the event start time. To reject photons from bremsstrahlung or from secondary interactions,
showers within an angle of 10° of the location of charged particles at the EMC are rejected. For π0 and ηγ, reconstruction, the γγ invariant mass is required to be within (0.115, 0.150) and (0.515, 0.575) GeV/c², respectively. To improve π0 and ηγ momentum resolution, a kinematic fit is performed to constrain the γγ invariant mass to the appropriate world average mass [6]. The four-momenta of the γγ combinations from the kinematic fit are used in further analysis. Since there are two η mesons in the final state of the D⁰ → ηγ decay, the π⁺π⁻η combination with invariant mass closer to the world average η' mass [6] is regarded as the η' candidate. Figure 2 illustrates the distributions of the γγ, π⁺π⁻π⁰ and π⁺π⁻η invariant masses for π⁰ and ηγ, D and η' candidates from data, after above requirements. In all cases, our nominal ΔE requirements are applied, and MBC is required to be in the interval (1.860, 1.870) GeV/c². See the next paragraph for details about the definitions of ΔE and MBC. For ηγ, D and η' signals, the π⁺π⁻π⁰ and π⁺π⁻η invariant masses are required to be within signal regions as shown in Table I.

For each selected D⁰ candidate, two variables, the energy difference ΔE = E_D⁰ - E_{beam}, and the beam energy constrained mass M_{BC} = √(E_{beam}²/c⁴ - |p_D⁰|²/c⁴) are calculated, where E_{beam} is the beam energy, E_D⁰ and |p_D⁰| are the energy and momentum of the D⁰ candidate in the e⁺e⁻ center-of-mass system. In the case of a correct D⁰ candidate, ΔE and M_{BC} will peak around zero and the nominal D⁰ mass [6], respectively. If multiple candidates are found only the combination with the smallest |ΔE| is kept in each single-tag mode. To suppress combinatorial background, mode-dependent ΔE requirements are imposed on the candidates. These correspond approximately to 3σ_{ΔE} around the fitted ΔE peak, where σ_{ΔE} is the fitted resolution of the ΔE distribution. To obtain single-tag D⁰ yields, we fit the M_{BC} distributions for each mode, as shown in Fig. 3.

In these fits, the D⁰ signal is modeled by the MC-simulated shape convolved with a Gaussian function representing the mass resolution difference between data and the MC simulation, and the combinatorial background is described by an ARGUS function [20] with endpoint fixed to 1.8865 GeV/c². The parameters of the Gaussian and ARGUS functions are determined in the fit. The resulting single-tag D⁰ yields, N_{sig}, are summarized in Table II.

For the decays containing an ηγ, D and η' meson in the final state, the non-ηγ, D and η' contribution in the ηγ, D or η' signal region is estimated by using the candidate events within the invariant mass sidebands listed in Table I. To obtain the single-tag D⁰ yields in the sideband regions, N_{sid} (see Table II), the corresponding M_{BC} distributions are fitted using a method similar to that described above. However, due to the low statistics and high backgrounds, only the parameters of the ARGUS function are left free, while the parameters of the smearing Gaussian function are fixed to the values extracted from the M_{BC} fit in the signal region. The non-π⁰ and non-ηγ contributions in the γγ invariant mass spectra are ignored since decays of the form D⁰ → γγX are highly suppressed, and therefore any combinatoric background under the π⁰ or ηγ signals will not peak in M_{BC}.

IV. RESULTS FOR BRANCHING FRACTIONS

Detailed MC studies show that, except for the nonresonant ηγ, D and η' background components, which are estimated from sideband regions, no other background processes peak in the M_{BC} distribution. We may thus determine the BF for the hadronic decay D⁰ → f via

\[ B(D⁰ → f) = \frac{N_{net}}{N_{tot}} \cdot \frac{1}{B_{int}}. \]

Here, N_{net} is the net signal yield, which is N_{sig} - N_{sid} (N_{sig}) when a sideband subtraction is (is not) applied to the

![FIG. 3. Fits to the M_{BC} distributions of the (a) D⁰ → αη, (b) D⁰ → ηγ, (c) D⁰ → η'π⁰, (d) D⁰ → ηη, (e) D⁰ → ηγ, and (f) D⁰ → η'η candidate events in data. The points with error bars are data. Intermediate mass spectra. The factor $n$ is four for the $D^0 \rightarrow \eta\pi\eta$ decay and two for other decays. The common factor of two accounts for charge conjugation, while the additional factor of two in the $D^0 \rightarrow \eta\pi\eta$ decay accounts for the two possible $\eta\pi\eta$ combinations per $D^0$ meson decay. $N_{\text{tot}}^{\pi^0}/D^0$ is the total number of $D^0\bar{D}^0$ pairs in data, which is determined to be $(10597 \pm 28 \pm 89) \times 10^7$ [21], $\epsilon$ is the detection efficiency, and $B_{\text{int}}$ denotes the decay BFs of the intermediate particles $x^0$, $\eta_{\gamma(x)}$, $\omega$ and $\eta'$ [6], which are not included in the detection efficiencies. The numbers of peaking background events in the $M_{\text{BC}}$ distributions are assumed to be equal between signal and sideband regions.

The detection efficiencies are estimated by analyzing signal MC events with the same procedure as data analysis, and are listed in Table II. Detailed studies show that the MC simulated events model data well.

Inserting the numbers of $N_{\text{int}}$, $n$, $N_{\text{tot}}^{\pi^0}/D^0$ [21], $\epsilon$ and $B_{\text{int}}$ [6] into Eq. (1), we obtain the resultant BFs shown in Table II, where the uncertainties are statistical only.

V. SYSTEMATIC UNCERTAINTY

Sources of systematic uncertainty in the BF measurements are summarized in Table III and discussed below.

(i) $N_{\text{tot}}^{\pi^0}/D^0$: The uncertainty of the total number of $D^0\bar{D}^0$ pairs, 0.9% [21], is considered as a systematic uncertainty for each decay.

(ii) $\pi^\pm$ tracking and PID: The $\pi^\pm$ tracking and PID efficiencies are studied by analyzing double-tagged hadronic $D\bar{D}$ events. The systematic uncertainty for the $\pi^\pm$ tracking and PID efficiencies each are assigned to be 1.0% per track. Tracking and PID systematics are each treated as fully correlated among themselves, but uncorrelated with each other.

(iii) $x^0$ and $\eta_{\gamma}$ reconstruction: The $x^0$ reconstruction efficiency is studied by analyzing double-tagged hadronic decays $D^0 \to K^-\pi^+$ and $K^-\pi^+\pi^-\pi^-$ versus $\bar{D}^0 \to K^+\pi^0\pi^0$ and $K^0\pi^0\pi^0$. The systematic uncertainties of both the $x^0$ reconstruction efficiency and the $\eta_{\gamma}$ reconstruction efficiency are found to be 2.0%.

(iv) $\omega$, $\eta_x$ or $\eta'$ signal window: The signal mass windows are widened by 2 MeV/$c^2$ for the $\omega$, $\eta_x$ or $\eta'$ used in $D^0 \to \eta\pi\eta$, $\eta'\pi^0$ or $\eta'\eta$ decays. We then re-determine the BFs, and the resulting differences, ranging from 0.5% to 3.3%, are taken as systematic uncertainties.

(v) $\Delta E$ requirement: Our $\Delta E$ requirements are widened from 3 to 3.5 times the fitted width, and we recalculate the BFs. The resulting differences, ranging from 3.0% to 8.7%, are taken as systematic uncertainties.

(vi) $M_{\text{BC}}$ fit: The uncertainties associated with the $M_{\text{BC}}$ fits are estimated by comparing the nominal BFs to the measured values with alternative signal yield fits. Variations include alternative total fit ranges of (1.8335,1.8865) or (1.8395,1.8865) GeV/$c^2$, alternative endpoints of 1.883 or 1.8867 GeV/$c^2$ for the ARGUS background function, and changes in the detailed method used to extract the MC signal shape. The quadratic sum of changes in the BFs, ranging from 1.5% to 5.3%, are taken as the systematic uncertainties.

(vii) Normalization of the backgrounds in signal/sideband regions (BKG normalization): Our nominal sideband subtraction for peaking backgrounds from nonresonant combinatorics in the $\omega$, $\eta_x$ and $\eta'$ spectra assumes that the equal area of the sideband and signal regions gives a correct normalization. This is investigated by using instead a scale factor obtained from fitting the corresponding $\pi^+\pi^-\pi^0$ or $\pi^+\pi^-\eta$ invariant mass spectra in data and integrating the background shape. The relative changes of the BFs, ranging from 0.4% to 1.1% are used as systematic uncertainties.

(viii) Intermediate BFs: The uncertainties on the quoted BFs for $\pi^0 \to \gamma\gamma$, $\eta \to \gamma\gamma$, $\omega \to \pi^+\pi^-\pi^0$, $\eta \to \pi^+\pi^-\pi^0$ and $\eta' \to \pi^+\pi^-\eta$ of 0.03%, 0.5%, 0.8%, 1.2% and 1.6% [6], respectively, are propagated as systematic uncertainties.

(ix) MC statistics: The uncertainties due to limited MC statistics used in determining efficiencies, varying from 0.5% to 1.3%, are included.
TABLE III. Systematic uncertainties (%) of the measured BFs, where com and ind denote the common and independent systematic uncertainties in the measured BFs for $D^0 \rightarrow \eta \eta_\ell$ and $D^0 \rightarrow \eta_\ell \eta_\ell$; the symbol “...” denotes that the uncertainty is not relevant.

Total: 6.9 8.3 9.6 5.4 6.3 11.2

All the individual systematic uncertainties are summarized in Table III. For the measurements of $D^0 \rightarrow \eta_\ell \eta_\ell$ and $D^0 \rightarrow \eta_\ell \eta_\ell$, the systematic uncertainties are classified into common and independent parts, necessary for the proper combination of these two measurements later. For each decay, the total systematic uncertainty is the quadratic sum of the individual ones.

VI. SUMMARY

Based on an analysis of the singly tagged events using the data sample of 2.93 fb$^{-1}$ taken at $\sqrt{s} = 3.773$ GeV with the BESIII detector, the BFs of the SCS decays $D^0 \rightarrow \omega \eta$, $\eta \pi^0$, $\eta' \pi^0$, $\eta_\ell \eta_\ell$ and $\eta' \eta'$ are measured, and are summarized in Table IV. Here, the first and second uncertainties are statistical and systematic, respectively. The presented $\mathcal{B}(D^0 \rightarrow \eta \eta_\ell)$ is the combination of two individual measurements, $\mathcal{B}(D^0 \rightarrow \eta_\ell \eta_\ell) = (2.18 \pm 0.09 \pm 0.12) \times 10^{-5}$ and $\mathcal{B}(D^0 \rightarrow \eta_\ell \eta_\ell) = (2.22 \pm 0.11 \pm 0.14) \times 10^{-5}$, by using the least squares method [22] and incorporating the common and independent uncertainties between the two modes as shown in Table III.

We compare the measured BFs and the world-average values, as shown in Table IV. The $\mathcal{B}(D^0 \rightarrow \omega \eta)$ is measured for the first time and its magnitude is consistent with the theoretical prediction [2-4], while the other four BFs are consistent with the world-averaged values within uncertainties, and are of comparable or significantly improved ($D^0 \rightarrow \eta \eta$) precision. These measurements provide helpful experimental data to improve our understanding of SU(3)-flavor symmetry breaking effects in $D$ decays [5].
