072004-2
Using $e^+e^- \rightarrow \Lambda_c^+ \bar{\Lambda}_c^-$ production from a 567 pb$^{-1}$ data sample collected by BESIII at 4.6 GeV, a full angular analysis is carried out simultaneously on the four decay modes of $\Lambda_c^+ \rightarrow pK_S^0, \Lambda \pi^+, \Sigma^+ \pi^0$, and $\Sigma^0 \pi^+$. For the first time, the $\Lambda_c^+$ transverse polarization is studied in unpolarized $e^+e^-$ collisions, where a nonzero effect is observed with a statistical significance of 2.1$\sigma$. The decay asymmetry parameters of the $\Lambda_c^+$ weak hadronic decays into $pK_S^0, \Lambda \pi^+$, $\Sigma^+ \pi^0$ and $\Sigma^0 \pi^+$ are measured to be $0.18 \pm 0.43$ (stat) $\pm 0.14$ (syst), $-0.80 \pm 0.11$ (stat) $\pm 0.02$ (syst), $-0.57 \pm 0.10$ (stat) $\pm 0.07$ (syst), and $-0.73 \pm 0.17$ (stat) $\pm 0.07$ (syst), respectively. In comparison with previous results, the measurements for the $pK_S^0$ and $\Sigma^0 \pi^0$ modes are consistent but with improved precision, while the parameters for the $\Lambda \pi^+$ and $\Sigma^+ \pi^0$ modes are measured for the first time.

DOI: 10.1103/PhysRevD.100.072004

I. INTRODUCTION

The study of the lightest charmed baryon $\Lambda_c^+$ is important for the understanding of the whole charmed baryon sector. In recent years, there has been significant progress in studying the $\Lambda_c^+$, both experimentally and theoretically [1,2]. This provides crucial information in detailed explorations of the singly charmed baryons ($\Sigma_c$, $\Xi_c$ and $\Omega_c$) [3,4], and further searches or discoveries of the doubly charmed baryons ($\Sigma_{cc}$ and $\Omega_{cc}$) [5,6]. Moreover, as the charmed baryon is the favored weak decay final state of $b$-baryons and its properties are inputs to study $b$-baryons, improved knowledge in the charm sector can contribute substantially to understanding the properties of $b$-baryons.

Some QCD-inspired charmed baryon models that have been developed [7] are the flavor symmetry model [8], factorization model [9], pole model [10], and current algebra framework [11]. As shown in Refs. [2,7], many of these models calculate $\Lambda_c^+$ decay rates in good agreement with experimental results. But the decay asymmetries predicted by these models for $\Lambda_c^+$ two-body hadronic weak decays do not agree very well.

The decay asymmetry parameter, $a_{\Lambda_c^+}$, in a weak decay $\Lambda_c^+ \rightarrow BP$ (B denotes a $J^P = \frac{1}{2}^-$ baryon and P denotes a
$J^P = 0^-$ pseudoscalar meson) is defined as $a_{BP}^+ = \frac{2Re(s\alpha)}{|s|^2 + |p|^2}$, where $s$ and $p$ stand for the parity-violating s-wave and parity-conserving p-wave amplitudes in the decay, respectively. Model calculations of $a_{BP}^+$ in $\Lambda_c^+ \rightarrow pK_S^0$, $\Lambda_c^+\pi^+$, $\Sigma^+\pi^0$, and $\Sigma^0\pi^+$ are quite uncertain, with $a_{BP}^{K_S}$ in the range $(-1.0, -0.49)$, $a_{BP}^{\Lambda_c^+}$ in $(-0.99, -0.67)$, $a_{BP}^{\Sigma^+\pi^0}$ in $(-0.76, -0.31)$ or $(0.39, 0.83)$, and $a_{BP}^{\Sigma^0\pi^+}$ in $(-0.76, -0.31)$ or $(0.43, 0.92)$ [10–18].

As predictions of $a_{BP}^+$ rely on the relative phase between the two amplitudes, the experimental measurements of the decay asymmetry parameters serve as very sensitive probes to test different theoretical models.

Experimentally, only $a_{\Lambda^+}\pi^+$ and $a_{\Lambda^0,S^0,\Sigma^0}\pi^0$ have been measured previously [19–22]. The measured value for $a_{\Lambda^+}\pi^+$ is $-0.45 \pm 0.32$, in contradiction with the predicted values in many theoretical models [10–15]. Therefore, it is important to carry out independent measurements of $a_{\Sigma^+\pi^0}$ to confirm the sign of $a_{\Sigma^+\pi^0}$ and test these models. Moreover, $a_{\Sigma^+\pi^0}$ and $a_{\Sigma^0\pi^+}$ should have the same value according to hyperon isospin symmetry [16], and any deviation from this expectation provides critical information on final state interactions in $\Lambda_c^+$ hadronic decays. All these models predict $a_{\Lambda^+}\pi^+$ consistent with the measured values, and it is necessary to further improve the experimental precision to discriminate between them.

In previous experiments, $\Lambda_c^+$ was assumed to be unpolarized, and the decay asymmetry parameter $a_{BP}^+$ was obtained by analyzing the longitudinal polarization from the weak two-body decay of the produced baryon $B$, such as $\Lambda \rightarrow p\pi^-$ and $\Sigma^+ \rightarrow p\pi^0$ for $a_{\Lambda^+}\pi^+$ and $a_{\Sigma^+\pi^0}$, respectively. However, the hypothesis of unpolarized $\Lambda_c^+$ may not be valid. There have been observations of transverse $\Lambda$ polarization in inclusive $\Lambda$ production in $e^+e^-$ collisions at 10.58 GeV [23] and in $e^+e^- \rightarrow \Lambda\Lambda$ at $J/\psi$ mass position [24], and it has been postulated that the produced $\Lambda_c^+$ could be polarized [25]. Further, as the polarization of the proton in the decay $\Lambda_c^+ \rightarrow pK^0_S$ is not accessible with the above method, a nonzero transverse polarization of the $\Lambda_c^+$ provides an alternative way to measure $a_{BP}^{K^0_S}$ [26].

In this work, we investigate for the first time the transverse polarization of the $\Lambda_c^+$ baryon in unpolarized $e^+e^-$ annihilations. We present for the first time measurements of the decay asymmetry parameters in $\Lambda_c^+$ decays into $pK^0_S$, $\Lambda\pi^+$, $\Sigma^+\pi^0$, and $\Sigma^0\pi^+$ based on a multidimensional angular analysis of the cascade-decay final states, which greatly improves the resulting precision. The data sample used in this analysis corresponds to an integrated luminosity of 567 pb$^{-1}$ collected with the BESIII detector at BEPCII at center-of-mass (CM) energy of 4.6 GeV.

Since the close proximity of the CM energy to the $\Lambda_c^+\Lambda_c^-$ mass threshold does not allow an additional hadron to be produced, $\Lambda_c^+\Lambda_c^-$ are always generated in pairs, which provides a clean environment to study their decays. When one $\Lambda_c^+$ is detected, another $\Lambda_c^-$ partner is inferred. Hence, to increase signal yields, we adopt a partial reconstruction method, in which only one $\Lambda_c^+$ is reconstructed out of all the final-state particles in an event. The charge conjugation modes are incorporated in the analysis, and they are always implied in the context, unless otherwise stated explicitly.

## II. DATA ANALYSIS

Details of the BESIII apparatus, the software framework and the Monte Carlo (MC) simulation sample have been given in Ref. [27]. The $\Lambda_c^+$ signal candidates are reconstructed through the decays into $pK^0_S$, $\Lambda\pi^+$, $\Sigma^+\pi^0$ and $\Sigma^0\pi^+$. Here, the intermediate particles $K^0_S$, $\Lambda$, $\Sigma^+$, $\Sigma^0$, and $\pi^0$ are reconstructed via the decays $K^0_S \rightarrow \pi^+\pi^-$, $\Lambda \rightarrow p\pi^-$, $\Sigma^+ \rightarrow p\pi^0$, $\Sigma^0 \rightarrow \gamma\Lambda$, and $\pi^0 \rightarrow \gamma\gamma$. The event selection criteria follow those described in Ref. [27], unless otherwise stated explicitly. To suppress the $\Lambda_c^+ \rightarrow pK^0_S$, $K^0_S \rightarrow \pi^0\pi^0$ events in the $\Sigma^+\pi^0$ candidate samples, the invariant mass of the $\pi^0\pi^0$ system is required to be outside the range $[400, 550]$ MeV/$c^2$.

For each signal decay mode, the yields are obtained from a fit to the beam-constrained mass ($M_{BC}$) distribution, $M_{BC} = \sqrt{E^2_{\text{beam}} - p^2_{\Lambda_c^+}}$, where $E_{\text{beam}}$ is the average beam energy and $p_{\Lambda_c^+}$ is the measured $\Lambda_c^+$ momentum in the CM system of the $e^+e^-$ collisions. If more than one candidate is reconstructed in the event, the one with the smallest energy

![FIG. 1. Fits to the $M_{BC}$ spectra of the signal candidates of (a) $\Lambda_c^+ \rightarrow pK^0_S$, (b) $\Lambda_c^+ \rightarrow \Lambda\pi^+$, (c) $\Lambda_c^+ \rightarrow \Sigma^+\pi^0$, and (d) $\Lambda_c^+ \rightarrow \Sigma^0\pi^+$. Points with error bars correspond to data, solid lines are the fitting curves, dashed lines describe the signal events distribution, dash-dotted lines show the Type-II backgrounds and shadowed areas correspond to Type-I backgrounds. Dashed and solid arrows show the sideband and signal regions, respectively.](#)
To evaluate the Type-I and Type-II background level, applied to the \( \Lambda_c^+ \) candidates, where the background shape is modeled by an ARGUS function whose width is left free and represents the difference in shapes are convolved with a common Gaussian function, derived from the signal MC simulation samples. These two nominal \( \Lambda_c^+ \) Ref. [26], constructed under the helicity basis, are used in where the full cascade decay chains are considered. The analysis, we take as an example the two-level cascade fit. To illustrate the helicity system defined in this
genre

III. DECAY ASYMMETRIES MEASUREMENT

The decay asymmetry parameters are determined by analyzing the multi-dimensional angular distributions, where the full cascade decay chains are considered. The full angular dependence formulas (4), (6), and (10) in Ref. [26], constructed under the helicity basis, are used in the fit. To illustrate the helicity system defined in this analysis, we take as an example the two-level cascade decay process \( \Lambda_c^+ \rightarrow \Lambda \pi^+ \), \( \Lambda \rightarrow p \pi^- \) following the level-0

process \( e^+ e^- \rightarrow \gamma^* \rightarrow \Lambda_c^+ \Lambda_c^- \). An analogous formalism is applied to the other \( \Lambda_c^+ \rightarrow BP \) decays.

Figure 2 illustrates the definitions of the full system of helicity angles for the \( \Lambda_c^+ \rightarrow \Lambda \pi^+ \) mode. In the helicity frame of \( e^+ e^- \rightarrow \Lambda_c^+ \Lambda_c^- \), \( \theta_0 \) is the polar angle of the \( \Lambda_c^+ \) with respect to the \( e^+ \) beam axis in the \( e^+ e^- \) CM system. For the helicity angles of the \( \Lambda_c^+ \rightarrow \Lambda \pi^+ \) decay, \( \phi_1 \) is the angle between the \( e^+ \Lambda_c^+ \) and \( \Lambda \pi^+ \) planes, and \( \theta_1 \) is the polar angle of the \( \Lambda \) momentum in the rest frame of the \( \Lambda_c^+ \) with respect to the \( \Lambda_c^+ \) momentum in the CM frame. The angle subscript represents the level numbering of the cascade signal decays. For the helicity angles describing the \( \Lambda \rightarrow p \pi^+ \) decay, \( \phi_2 \) is the angle between the \( \Lambda \pi^+ \) plane and \( p \pi^- \) plane and \( \theta_2 \) is the polar angle of the proton momentum with respect to opposite direction of \( \pi^+ \) momentum in the rest frame of \( \Lambda_c^+ \). For the three-level cascade decays \( \Lambda_c^+ \rightarrow \Sigma^0 \pi^+, \Sigma^0 \rightarrow \Lambda \gamma, \Lambda \rightarrow p \pi^- \) process, \( \phi_3 \) is the angle between the \( \Lambda \gamma \) and \( p \pi^- \) planes, while \( \theta_3 \) is the polar angle of the proton with respect to the opposite direction of the photon momentum (from \( \Sigma^0 \rightarrow \Lambda \gamma \)) in the rest frame of \( \Lambda \).

In Ref. [26], we define \( \Delta_0 \) as the phase angle difference between two individual helicity amplitudes, \( H_{1,2} \), for the \( \Lambda_c^+ \) production process \( \gamma^* \rightarrow \Lambda_c^+ (\lambda_1) \Lambda_c^- (\lambda_2) \) with total helicities \( |\lambda_1 - \lambda_2| = 0 \) and 1, respectively. In the case where one-photon exchange dominates the production process, \( \Delta_0 \) is also the phase between the electric and magnetic form factors of the \( \Lambda_c^+ \) [25,29]. The transverse polarization observable of the produced \( \Lambda_c^+ \) can be defined as

\[
P_T(\cos \theta_0) \equiv \sqrt{1 - \alpha_0^2 \cos \theta_0 \sin \theta_0 \sin \Delta_0},
\]

whose magnitude varies as a function of \( \cos \theta_0 \), and \( \alpha_0 \) is the angular distribution parameter of charmed baryon defined by the helicity amplitudes \( \alpha_0 = (|H_{1/2,1/2}^2| - 2|H_{1/2,1/2}^2|)/ (|H_{1/2,1/2}^2|^2 + 2|H_{1/2,1/2}^2|^2) \). Similarly, two parameters, \( \alpha_{BP} \) and \( \Delta_1^BP \), describe the level-1 decays \( \Lambda_c^+ \rightarrow \Lambda \pi^+, \Sigma^+ \pi^0, \) and \( \Sigma^0 \pi^+ \), where \( \Delta_1^BP \) is the phase angle difference between the two helicity amplitudes in the \( BP \) mode. The Lee-Yang parameters [26,30] can be obtained with the relations

\[
\beta_{BP} = \sqrt{1 - (\alpha_{BP}^2)^2 \sin \Delta_1^BP},
\]

\[
\gamma_{BP} = \sqrt{1 - (\alpha_{BP}^2)^2 \cos \Delta_1^BP}.
\]

In the angular analysis, the free parameters describing the angular distributions for the four data sets are determined from a simultaneous unbinned maximum likelihood fit, as \( \alpha_0 \) and \( \Delta_0 \) are common. The likelihood function is constructed from the probability density function (PDF) jointly by

\[
\mathcal{P}(\cos \theta_0, \Delta_0) \equiv \sqrt{1 - \alpha_0^2 \cos \theta_0 \sin \theta_0 \sin \Delta_0},
\]

where \( \alpha_0 \) is the angular distribution parameter of charmed baryon defined by the helicity amplitudes \( \alpha_0 = (|H_{1/2,1/2}^2| - 2|H_{1/2,1/2}^2|)/ (|H_{1/2,1/2}^2|^2 + 2|H_{1/2,1/2}^2|^2) \). Similarly, two parameters, \( \alpha_{BP} \) and \( \Delta_1^BP \), describe the level-1 decays \( \Lambda_c^+ \rightarrow \Lambda \pi^+, \Sigma^+ \pi^0, \) and \( \Sigma^0 \pi^+ \), where \( \Delta_1^BP \) is the phase angle difference between the two helicity amplitudes in the \( BP \) mode. The Lee-Yang parameters [26,30] can be obtained with the relations

\[
\beta_{BP} = \sqrt{1 - (\alpha_{BP}^2)^2 \sin \Delta_1^BP},
\]

\[
\gamma_{BP} = \sqrt{1 - (\alpha_{BP}^2)^2 \cos \Delta_1^BP}.
\]

\[ L_{\text{data}} = \prod_{i=1}^{N_{\text{data}}} f_S(\vec{\xi}) . \quad (3) \]

Here, $f_S(\vec{\xi})$ is the PDF of the signal process, $N_{\text{data}}$ is the number of the events in data and $i$ is event index. The signal PDF $f_S(\vec{\xi})$ is formulated as

\[ f_S(\vec{\xi}) = \frac{e^{\vec{\xi}} |M(\vec{\xi}; \vec{\eta})|^2}{\int e^{\vec{\xi}} |M(\vec{\xi}; \vec{\eta})|^2 d\vec{\xi}}, \quad (4) \]

where the variable $\vec{\xi}$ denotes the kinematic angular observables, and $\vec{\eta}$ denotes the free parameters to be determined. $M(\vec{\xi})$ is the total decay amplitude [26] and $e(\vec{\xi})$ is the detection efficiency parametrized in terms of the kinematic variables $\vec{\xi}$. The background contribution to the joint likelihood is subtracted according to the calculated likelihoods for the type-I background based on inclusive MC simulations and for the type-II background according to the $M_{\text{BC}}$ sideband. With a MC sample of sufficiently large size, the integration of the normalization factor is calculated as follows

\[ \int e^{\vec{\xi}} |M(\vec{\xi}; \vec{\eta})|^2 d\vec{\xi} = \frac{1}{N_{\text{gen}}} \sum_{k_{\text{MC}}} |M(\vec{\xi}_k; \vec{\eta})|^2, \quad (5) \]

where $N_{\text{gen}}$ is the total number of MC-simulated signal events. $N_{\text{MC}}$ is the number of the MC signal events survived from the full selection criteria and $k_{\text{MC}}$ is its event index.

Minimization of the negative logarithmic likelihood with background subtraction over all the four signal processes is carried out using the MINUIT package [31]. Here, $\alpha_0$ is fixed to the known value $-0.20$ [29]. For the charge-conjugation $\bar{\Lambda}_c$ decays, under the assumption of $CP$ conservation, $\bar{\Delta}_0 = \Delta_0$, $\alpha_{BP} = -\alpha_{BP}^{\text{PDG}}$, and $\Delta_{BP}^{\text{rad}} = -\Delta_{BP}^{\text{rad}}$. The decay asymmetry parameter $\alpha_{\Lambda}$ for $\Lambda \rightarrow p\pi^-$ is taken from the recent BESIII measurement [24] and $\alpha_{\Sigma^+}$ for $\Sigma^+ \rightarrow p\pi^0$ from the Particle Data Group (PDG) [2]. In the fit, the statistical uncertainty of parameters in question is determined by the MINUIT package, which corresponds to the change of one-standard-deviation value of log-likelihood function. From the fit, we obtain $\sin \Delta_0 = -0.28 \pm 0.13$ (stat.) which differs from zero with a statistical significance of 2.1σ according to a likelihood ratio test. This indicates that transverse polarization $P_T$ of the $\Lambda_c^-$ is nonzero when $\sin(2\theta_0) \neq 0$. The numerical fit results are given in Table I, together with the calculated $\gamma_{BP}$ and $\beta_{BP}$.

In Fig. 3, the fit results are illustrated using several projection variables. The data are compared with the MC generated events reweighted according to the fit.

For the $\Lambda_c^- \rightarrow \Lambda \pi^+$ and $\Sigma^+ \pi^0$ decays, if all angles are integrated over except for the angle $\theta_2$, the decay rate becomes [32]

\[ \frac{dN}{d\cos \theta_2} \propto 1 + \alpha_{\Lambda}^{\text{sin}}(\Sigma^+ \pi^0) \alpha_{\Lambda}(\Sigma^+) \cos \theta_2 . \quad (6) \]

FIG. 3. $\cos \theta_2$ distributions in (a) $\Lambda \pi^+$, and (b) $\Sigma^+ \pi^0$; (c) average value of $\cos \theta_3$ as a function of $\cos \theta_2$; and (d) average value of $\cos \theta_2$ as a function of $\cos \theta_3$ in $\Lambda_c^- \rightarrow \Sigma^0 \pi^+$; (e) $\langle\sin(\alpha_{BP}) \sin \theta_1 \sin \phi_1 \rangle$ as a function of $\cos \theta_2$ for all the four signal channels. Points with error bars correspond to data; (red) solid lines represent the MC-determined shapes taking into account the fit results; (green) dash-dotted lines represent the Type-II background and shaded histograms show the type-I background.
Equation (6) shows a characteristic longitudinally polarized of the produced $\Lambda (\Sigma^+)$ from the $\Lambda_+^0$ decays, and the asymmetry of $\alpha_2$ distribution reflects the product of the decay asymmetries $\alpha_{2\Lambda}^+\alpha_A(\alpha_{2\Sigma^+}^+\alpha_{2\pi^0})$ [33]. The distributions of $\alpha_2$ in the $\Lambda_+^0\rightarrow \Lambda\pi^+$ and $\Sigma^+\pi^0$ modes are shown in Figs. 3(a) and (b), respectively. The drop at the right side in Fig. 3(b) is due to the $K_L^0\rightarrow \pi^0\pi^0$ veto.

For the $\Lambda_+^0\rightarrow \Sigma^0\pi^+$ decay, the correlations of $\cos\theta_2$ and $\cos\theta_3$ in the subsequent level-2 decay $\Sigma^0\rightarrow \gamma\Lambda$ and level-3 decay $\Lambda\rightarrow p\pi^-$, are shown in Figs. 3(c) and (d), respectively. The correlation of the average value of $\cos\theta_i$ satisfies the relation

$$\langle \cos \theta_i \rangle = -\frac{1}{6} \alpha_{2\Sigma^+}^+ \alpha_{2\Lambda} \cos \theta_j,$$

with $(i, j) = (2, 3)$ or $(3, 2)$.

If the full expressions for the joint angular distributions (Ref. [26]) are integrated over the angles of the level 2 and 3 decay products, the remaining partial decay rate $W$ is

$$W = 1 + \alpha_0 \cos^2 \theta_0 + \rho_T \alpha_{BP} \cos \theta_1 \sin \phi_1.$$  

Therefore, in a given $\cos \theta_0$ interval,

$$\langle \sin \theta_1 \sin \phi_1 \rangle = \frac{\int_0^{\theta_1} \int_0^{\phi_1} \sin \theta_1 \sin \phi_1 W \cos \theta_1 d\phi_1}{\int_0^{\theta_1} \int_0^{\phi_1} W \cos \theta_1 d\phi_1}$$

is directly proportional to $\alpha_{BP} \rho_T \cos \theta_0 / (1 + \alpha_0 \cos^2 \theta_0)$ for the acceptance corrected data. In Fig. 3(e), the effect of the transverse polarization $\rho_T \cos \theta_0$ is illustrated by plotting the average value $\langle \sin (\alpha_{BP}) \sin \theta_1 \sin \phi_1 \rangle$ from all four decay modes and including both particles and antiparticles. The sign function of the measured decay asymmetry parameter, $\text{sign}(\alpha_{BP})$, is used to avoid the cancellation of contributions from the opposite charge modes.

### IV. SYSTEMATIC UNCERTAINTIES

The systematic uncertainties arise mainly from the reconstruction of final state tracks, $K_L^0\rightarrow \pi^0\pi^0$ veto, $\Delta E$ requirement, signal $M_{BC}$ selections and background subtraction. The contributions are summarized in Table II. The uncertainty due to the input $\alpha_0$ is found to be negligible, after considering the experimental uncertainty [29]. Systematic uncertainties from different sources are combined in quadrature to obtain the total systematic uncertainties.

To understand the reconstruction efficiencies in data and MC simulations, a series of control samples are used for different final states. The proton and charged pion are studied based on the channel $J/\psi \rightarrow p\bar{p}\pi^+\pi^-$, photon on $e^+e^-\rightarrow \gamma p\bar{p} $ [34], $\pi^0$ on $\psi(3686)\rightarrow \pi^0\pi^0 J/\psi$ and $e^+e^-\rightarrow \omega \pi^0$, $\Lambda$ on $J/\psi \rightarrow pK^+\Lambda$ and $J/\psi \rightarrow \Lambda \Lambda^0$ [35], and $K_0^0$ on $J/\psi \rightarrow K^+(892)^+K^-$, $K^-(892)^+ \rightarrow K_0^0\pi^+\pi^0$ and $J/\psi \rightarrow \phi K_0^0 K^+\pi^-\pi^0$ [36]. The efficiency differences between data and MC simulations are used to reweight the summed likelihood values. The changes of the fit results after likelihood minimization are taken as systematic uncertainties.

The uncertainties due to the $K_L^0\rightarrow \pi^0\pi^0$ veto in $\Sigma^+\pi^0$ candidate events are evaluated by taking the maximum changes with respect to the nominal results when varying the $\pi^0\pi^0$ veto range. A similar method is applied when estimating the systematic uncertainties from the signal $\Delta E$ and $M_{BC}$ selection criteria. The background contributions are modeled with the sideband control samples and the inclusive MC samples, and then subtracted from the data likelihood function. The associated uncertainties are studied by varying the sideband range and adjusting the scaling factors of the two background components. The altered scaling factors are obtained by changing the background line signatures within their 1σ uncertainties from the fits to the $M_{BC}$ distribution. The resultant maximum changes of the fit results are taken as corresponding systematic uncertainties.

### V. SUMMARY

To summarize, based on the 567 pb$^{-1}$ data sample collected from $e^+e^-$ collisions at a CM energy of 4.6 GeV, a simultaneous full angular analysis of four decay modes of $\Lambda^+_c \rightarrow pK^0_S$, $\Lambda^+\pi^+$, $\Sigma^+\pi^0$, and $\Sigma^0\pi^+$ from the $e^+e^-\rightarrow \Lambda^+_c \Lambda^-_c$ production is carried out. We study the $\Lambda^+_c$ transverse polarization in unpolarized $e^+e^-$ collisions for the first time, which gives $\sin \Delta_0 = -0.28 \pm 0.13 \pm 0.03$ with a statistical significance of 2.1σ. This information will help in understanding the production mechanism of the charmed baryons in $e^+e^-$ annihilations. With availability of the transverse polarization measurement, the decay asymmetry parameter in $\Lambda^+_c \rightarrow pK^0_S$ becomes accessible experimentally. Moreover, this improves the precision in

### TABLE II. Summary of the systematic uncertainties. $A$, $B$, $C$ and $D$ stand for the modes of $pK^0_S$, $\Lambda\pi^+$, $\Sigma^+\pi^0$, and $\Sigma^0\pi^+$, respectively.

determining the decay asymmetry parameters in \( \Lambda^+_\alpha \rightarrow \Lambda \pi^+ \), \( \Sigma^+_\alpha \pi^0 \), and \( \Sigma^0 \pi^+ \), as listed in Table I.

The parameters \( \alpha_{pK}^{+\pi_0} \) and \( \alpha_{pK}^{-\pi^+} \) are measured for the first time. The measured \( \alpha_{pK}^{+\pi_0} \) and \( \alpha_{pK}^{-\pi^+} \) parameters are consistent with previous measurements, but with much improved precisions (by a factor of 3 for \( \alpha_{\Sigma^-\pi^0} \)). The negative sign of the \( \alpha_{\Sigma^-\pi^0} \) parameter is confirmed and differs from the positive predictions [10–15] by at least \( \delta \sigma \), which rules out those model calculations. The measured \( \alpha_{\Sigma^-\pi^0} \) and \( \alpha_{\Sigma^-\pi^+} \) values agree well, which supports hyperon isospin symmetry in \( \Lambda^+_\alpha \) decay. For the results on \( \alpha_{pK}^{+\pi_0} \), \( \alpha_{pK}^{-\pi^+} \), and \( \alpha_{pK}^{+\pi^+} \) listed in Table I, at present no model gives predictions fully consistent with all the measurements. These improved results in \( \Lambda^+_\alpha \) decay asymmetries provide essential inputs for the \( b \)-baryon decay asymmetry measurements to be performed in the future.

**ACKNOWLEDGMENTS**

The BESIII collaboration thanks the staff of BEPCII and the IHEP computing center for their strong support.
